

Dyad Geopolitical Scores – Variable Codebook

Dataset Overview

File: `dyad_geopolitical_scores.zip` – a compressed archive (~28 MB) containing a single CSV, `dyad_geopolitical_scores.csv` (~93 MB uncompressed). Unzip before loading.

Unit of observation: Dyad-year (undirected, alphabetically ordered by ISO 3166-1 alpha-3 code)

Time coverage: 1950–2024 (75 years)

Country coverage: All 193 UN member states, comprising 18,528 unique dyads

Total observations: 1,389,600 (18,528 dyads $\times$ 75 years)

Panel type: Balanced (all dyad-year cells present; zero-event cells recorded as 0)

Source data: Global Geopolitical Events (GGE) Database, v1

Total events: 833,485 bilateral political events¹

Dyad-years with at least one event: 417,863 (30.1%)

Scope note: This release provides full-coverage **aggregate** alignment scores for all 18,528 UN-member dyads. The empirical samples of *Fan (2025)*, “*Measuring Geopolitical Alignment and Economic Growth*” (24 major economies) and *Fan, Wo, and Xiang (2025)*, “*Geopolitical Barriers to Globalization*” (32 major economies) are subsets of this panel. The domain decomposition and structural analysis remain forthcoming with the companion measurement paper, *Fan, Liu, and Xiang (2026)*, “*The Structure of International Order, 1950–2024*”; the aggregate panel here does not depend on that paper’s release.

Variable Definitions

Identifiers

Variable	Type	Description
<code>dyad</code>	String	Country pair identifier in alphabetical order (e.g., CHN-USA, DEU-FRA)
<code>country1_code</code>	String	ISO3 code of the first country (alphabetically earlier)

¹The `number_of_events` column counts events with a valid Goldstein score and sums to 833,528 across the panel; the 833,485 headline additionally requires a CAMEO root code.

Variable	Type	Description
country2_code	String	ISO3 code of the second country
year	Integer	Calendar year (1950–2024)

Primary Geopolitical Measures

Variable	Type	Range	Description
geo_score	Float	$[-1, 1]$	Static geopolitical score. Annual average of Goldstein Scale values divided by 10. Missing if no events observed.
geo_score_dyn	Float	$[-1, 1]$	Dynamic geopolitical score. Exponentially weighted score incorporating historical information with depreciation rate $\delta = 0.3$. Never missing; decays toward 0 during periods without events.
geo_score_ma	Float	$[-1, 1]$	Moving average geopolitical score. Event-weighted average of <code>geo_score</code> over a 3-year window ($t - 2$ to t). Missing if no valid observations in window.

Auxiliary Variables

Variable	Type	Range	Description
number_of_events	Integer	$[0, \infty)$	Count of bilateral geopolitical events in the given year
cum_events	Float	$[0, \infty)$	Effective cumulative event count with exponential depreciation
weight	Float	$[0, 1]$	Updating weight $\phi_{ij,t}$ assigned to the current year's score in the dynamic calculation

Score Construction

Static Score

Let $\{s_{ij,t}^n\}_{n=1}^{\tilde{N}_{ij,t}}$ denote the Goldstein scores for the set of events between countries i and j in year t , where $\tilde{N}_{ij,t}$ is the number of events. The yearly average event score, normalized to the $[-1, +1]$

interval, is:

$$\tilde{S}_{ij,t} = \frac{1}{\tilde{N}_{ij,t}} \sum_{n=1}^{\tilde{N}_{ij,t}} s_{ij,t}^n / 10$$

This corresponds to the variable `geo_score`. It is missing (NaN) for dyad-years with no observed events.

Dynamic Score

The dynamic score balances the contemporaneous impact of political events with the institutional memory that characterizes interstate relations. When events are observed ($\tilde{N}_{ij,t} > 0$):

$$S_{ij,t} = (1 - \phi_{ij,t}) \cdot S_{ij,t-1} + \phi_{ij,t} \cdot \tilde{S}_{ij,t}$$

where the updating weight and effective cumulative event count are:

$$\phi_{ij,t} = \frac{\tilde{N}_{ij,t}}{N_{ij,t}}, \quad N_{ij,t} = (1 - \delta) N_{ij,t-1} + \tilde{N}_{ij,t}$$

When no events are observed ($\tilde{N}_{ij,t} = 0$), the update equation does not apply; instead, both the score and effective event count decay:

$$S_{ij,t} = (1 - \delta) S_{ij,t-1}, \quad N_{ij,t} = (1 - \delta) N_{ij,t-1}$$

Initialization. For the first year of each dyad ($t = t_0$): $S_{ij,t_0} = \tilde{S}_{ij,t_0}$ and $N_{ij,t_0} = \tilde{N}_{ij,t_0}$. When the initial year has no events, $S_{ij,t_0} = 0$ and $N_{ij,t_0} = 0$.

The depreciation rate is set to $\delta = 0.3$. The updating weight $\phi_{ij,t}$ determines how responsive the score is to new information: country pairs with long interaction histories have large $N_{ij,t}$, so any single year's events receive a small weight, reflecting the difficulty of fundamentally shifting a deeply established relationship. Conversely, pairs with sparse histories update more rapidly.

This corresponds to the variable `geo_score_dyn`. It is never missing; it equals 0 for dyads with no prior events and decays toward 0 during periods without events.

Moving Average Score

The moving average score is an event-weighted average of `geo_score` over a 3-year window ($t - 2$ to t):

$$S_{ij,t}^{\text{ma}} = \frac{\sum_{k=t-2}^t \tilde{N}_{ij,k} \cdot \tilde{S}_{ij,k}}{\sum_{k=t-2}^t \tilde{N}_{ij,k}}$$

where the sum includes only years with non-missing scores. Missing if no events occur in the entire window.

Key Parameters

Parameter	Value	Description
δ	0.3	Depreciation rate for dynamic scores and cumulative events
MA window	3 years	Moving average window ($t - 2$ to t)

Goldstein Scale Interpretation

The underlying Goldstein Scale ranges from -10 (maximum conflict) to $+10$ (maximum cooperation). All `geo_score` variants are normalized by dividing by 10:

Score range	Interpretation
-1.0 to -0.6	Severe conflict (military attacks, war, use of force)
-0.6 to -0.3	Significant hostility (military threats, sanctions, breaks in relations)
-0.3 to 0.0	Minor conflict (diplomatic protests, recalls, verbal hostility)
0.0 to $+0.3$	Neutral to mild cooperation (routine diplomatic exchanges, visits)
$+0.3$ to $+0.6$	Moderate cooperation (agreements, treaties, joint statements)
$+0.6$ to $+1.0$	Strong cooperation (military alliance, economic integration, extensive aid)

Event Data Methodology

Overview

The underlying event data were compiled by a large language model (Gemini 2.5 Pro) following a structured prompt. Each event represents a distinct significant bilateral political interaction between two countries in a given year.

Event Identification Pipeline

The LLM follows a 5-step analytical procedure for each dyad-year:

1. **Entity verification.** Confirm that both countries existed as the specified political entities in the target year; if not, identify the appropriate historical predecessor (e.g., Soviet Union before December 1991).
2. **Systematic search.** Search across all six event domains (below) using official government sources, international organizations, major news archives, and academic sources.
3. **Event coding.** Classify each event by category (A1–F7), assign CAMEO quad class and root code, and calibrate a Goldstein score (-10 to $+10$).

4. **Relationship assessment.** Assign an overall annual assessment using a 9-point ordinal scale ranging from *State of War / Active Conflict* to *Alliance*.
5. **Structured output.** Generate a validated JSON object with 17 required fields per event.

Event Taxonomy

Events are classified into 6 top-level domains with 23 subcategories:

A. Economic Relations (6 subcategories)

- A1. Trade Policy and Market Access – tariffs, non-tariff barriers, trade agreements
- A2. Financial and Monetary Relations – financial sanctions, monetary cooperation, investment controls
- A3. Economic Coercion and Incentives – comprehensive sanctions, export controls, economic aid
- A4. Strategic Economic Sectors – energy, technology/digital, critical resources
- A5. Economic Integration and Infrastructure – BRI/competing programs, supply chains, regional arrangements
- A6. Other Economic Events – market access issues, boycotts, gray zone actions

B. Diplomatic and Political Relations (4 subcategories)

- B1. Formal Diplomatic Engagement – embassy actions, ambassador recalls, diplomatic protests
- B2. High-Level Political Interactions – summits, ministerial meetings, strategic dialogues
- B3. Public Diplomacy and Rhetoric – policy speeches, parliamentary resolutions, propaganda
- B4. Cultural and Educational Diplomacy – cultural agreements, scholarship programs, academic exchanges

C. Security and Defense (3 subcategories)

- C1. Military Cooperation and Competition – defense agreements, arms sales, joint exercises
- C2. Security Incidents and Responses – border skirmishes, airspace violations, territorial claims
- C3. Intelligence and Cyber – espionage, cyber attacks, intelligence sharing

D. Legal, Territorial, and Movement (3 subcategories)

- D1. International Legal Actions – ICJ/WTO cases, extradition, legal cooperation
- D2. Territorial and Maritime Issues – EEZ disputes, border demarcation, sovereignty claims
- D3. Movement of People – visa policies, migration agreements, travel bans

E. Multilateral and Global Governance (2 subcategories)

- E1. International Organizations – UN system, regional organization actions
- E2. Global Issues Cooperation/Competition – climate, health, human rights

F. Other Significant Events (5 subcategories)

- F1. Historical and Symbolic Events – apologies, memorial visits, symbolic gestures
- F2. Natural Disasters and Humanitarian Crises – disaster response, crisis management
- F3. Sports and Major Events – Olympic boycotts, major event hosting
- F4. Technology and Space – joint missions, technology disputes

- F5–F7. Environmental, Communications, and Other – transboundary issues, media relations, other interactions

CAMEO Framework

Each event is classified using the Conflict and Mediation Event Observations (CAMEO) framework into one of four quad classes:

Quad class	CAMEO root codes	Examples
Verbal Cooperation	01–05	Public statements, appeals, diplomatic cooperation
Material Cooperation	06–08	Material aid, economic cooperation, concessions
Verbal Conflict	09–14	Demands, disapproval, threats, protests
Material Conflict	15–20	Force posture, reduced relations, coercion, assault

The 20 CAMEO root codes provide a standardized two-digit classification of event types, enabling comparison with other political event datasets.

Goldstein Scale

The Goldstein scale assigns each event a cooperation–conflict intensity score:

- **–10 to –8:** Highly conflictual (military attacks, mass violence)
- **–8 to –5:** Threats, coercion, severe sanctions
- **–5 to –2:** Diplomatic protests, rejections, minor sanctions
- **–2 to 0:** Mild disagreements, negative rhetoric
- **0 to +2:** Initial positive gestures, routine exchanges
- **+2 to +5:** Consultations, cooperative intent, diplomatic meetings
- **+5 to +8:** Significant aid, major agreements, material cooperation
- **+8 to +10:** Major concessions, peace agreements, alliance formations

Scores are calibrated against CAMEO root codes and adjusted for bilateral context.

Usage Notes

1. **Balanced panel.** The dataset includes all 18,528 dyad-year combinations within the time range, including years with no events (`number_of_events` = 0). Approximately 70% of dyad-years have zero events, reflecting the sparsity of bilateral interactions among distant or small-state pairs.

2. **Dyad ordering.** Dyads are undirected. The two ISO3 codes are always arranged alphabetically (e.g., CHN-USA, never USA-CHN).
 3. **Historical entities.** Country codes reflect present-day ISO3 assignments. Events involving predecessor states (e.g., the Soviet Union before 1991) are coded under the successor state's code (e.g., RUS).
 4. **Recommended usage:**
 - Use `geo_score_dyn` for cross-sectional analysis, as it reflects the cumulative geopolitical alignment status of each dyad at a given point in time.
 - Use `geo_score_dyn` for time-series analysis, with `geo_score` as a robustness check to verify that results are not driven by the smoothing procedure.
 - Use `geo_score_ma` as an additional robustness check or to reduce measurement error from year-to-year volatility.
 5. **Interpretation of sign:**
 - Negative values indicate conflict, hostility, or deteriorating relations.
 - Positive values indicate cooperation, partnership, or improving relations.
 - Values near zero indicate neutral or minimal interaction.
